ABSTRACT

The focus of this thesis is to determine if the application of Plant Growth Regulators (PGR's) to frequently mowed semi-improved areas can minimize the total annual mowing costs at Naval Air Station Cecil Field, Florida and Naval Air Station Jacksonville, Florida.

The highest potential savings are in areas where the frequency of mowing is weekly or biweekly. In areas where the mowing frequency is one time per month, the savings approach a breakeven.

The results indicate considerable cost savings can be realized at both naval air stations if a well-planned PGR application program is implemented.

I. INTRODUCTION

A. BACKGROUND

Grounds maintenance requirements at U.S. Naval activities are time consuming and expensive. Mechanical mowing of grasses consumes a sizeable portion of a typical activity's grounds maintenance budget. Expenditures in this area within DoD are estimated to exceed \$200 million annually [Ref. 1]. Alternatives to mowing grasses exist and have been found in many instances to be cost effective. One of the alternatives being used by both the private sector and various local, state and federal agencies is the application of plant growth regulators (PGR's) to various grasses and shrubs.

B. RESEARCH OBJECTIVE

The objective of this thesis is to analyze the cost effectiveness of using a plant growth regulator (PGR) to minimize an activity's annual grounds maintenance costs.

The intention of this is twofold:

- A facility manager will be able to use the analytical results of this thesis to determine his or her best action.
- A facility manager will be able to apply the methodology used in this thesis to perform a cost/benefit study.

C. RESEARCH QUESTION

The primary research question is: Will the application of a plant growth regulator (PGR) result in a sufficiently large reduction in an activity's total annual grass cutting costs? Subsidiary research questions are as follows:

- Which mowed areas at an activity should be considered for the application of PGR's?
- Should PGR's be applied throughout the growing season?
- Does the Naval Facilities Engineering Command (NAVFAC) recommend the use of PGR's to its field activities?

D. SCOPE, LIMITATIONS AND ASSUMPTIONS

This thesis focuses on the results of PGR research and applies those results to cost/benefit analyses of two typical naval activities. Bahiagrass is the common warm season grass at the two activities. The variety of grasses found at other Naval activities will vary, depending on geographic location and climate. The recommended PGR to be applied and its effectiveness will also vary depending on the activity's location. Therefore, it is essential that a PGR application program be tailored to a specific activity by professionals with knowledge of the local turf grasses and PGR's.

There are variances documented in the PGR research data from one year to the next [Ref. 1]. The facility manager should consider these variances and consult with his

forester, or resident expert, on PGR's before making a decision on their use.

The field of knowledge relating to PGR's is growing each year. Reliance on several expert sources for information is recommended before the decision is made regarding an annual PGR application program.

E. LITERATURE REVIEW AND METHODOLOGY

Information for this thesis was obtained primarily through a detailed literature review. A secondary source of information was field research.

1. Literature Review

A thorough review of existing research data on PGR's was performed. Included in this review were periodicals, professional journals, conference papers, manufacturers' fact sheets and research data collected by the U.S. Army Corps of Engineers.

Information on PGR's included data compiled from basic field research. This data showed the results from applying different types of PGR's at different concentrations on various grasses. Other information included articles from PGR users and addressed the effectiveness of PGR's. These users included state highway departments, county agencies, airport authorities, private landscapers, and golf course maintenance professionals.

2. Field Research

Field research included telephone interviews with research personnel and present and potential users of PGR's. These interviews were used to clarify and confirm information as well as obtain any new information on the subject.

F. ORGANIZATION OF STUDY

Chapter II discusses the background on PGR's and identifies factors which are critical to establishing an effective PGR application program. Chapter III details the cost/benefit study performed at two Naval activities in the Southeast United States. Chapter IV provides conclusions and recommendations based on this study.

II. BACKGROUND OF PLANT GROWTH REGULATORS

In the late 1940's the U.S. Rubber Company developed a synthetic PGR for use on trees, shrubs and turf. This PGR was maleic hydrazide (MH). Its effectiveness was varied and led to the development of other PGR's in the years to follow. Today's products are much improved, providing more consistent results in controlling the growth of vegetation. [Ref. 2] Chemicals used as PGR's include sulfometuron, methyl methyl2, glyphosphate, maleic hydrazide, and amidochlor. Manufacturers such as Dupont, 3M, Monsanto, and Uniroyal market these chemicals under various trade names. Some of the problems which exist today with PGR's include:

- discoloration (yellowing) of turf after application.
- thinning of turf.
- poor wear tolerance.
- decreased disease tolerance.
- different effects on turf with mixed stands of foliage.

A. CATEGORIES OF PGR'S

Plant growth regulators fall into two basic categories. Foliarly-absorbed compounds are taken in through the foliage. To be effective these PGR's must remain in contact with the leaf for several hours. The second type is the root/crown-absorbed PGR. Regulators of this type must be

taken in through the crown or root system in order to be effective. Adequate rainfall or an irrigation system is necessary for the root system to properly absorb this type of PGR. [Ref. 2]

B. DESIRED TRAITS IN A PGR

The ideal PGR has not been developed but if it existed it would have the following traits: [Ref. 3]

- Reasonably long residual activity.
- Inhibition of seedhead and stalk formation.
- No objectionable discoloration or chemical burning of the turf.
- Control or suppression of broadleaf leaves.
- No reduction in turfgrass quality with repeated usage.
- Low toxicity to desirable vegetation and no long-term residual.

C. CATEGORIES OF TURF

There are three turf classifications which are currently maintained by mechanical mowing. These include fine turf, medium turf and rough turf. Fine turfs include home lawns, lawns around office buildings and golf course fairways. Medium turfs include school grounds, athletic fields and cemeteries. Since the application of PGR's leads to poor turf color (yellowing) and other unpredictable effects it is not widely used on fine and medium turfs. Rough turfs include airport clear areas, highway medians, road ditches, some industrial grounds, ammunition storage areas and golf

course roughs. The approximate frequency of mechanical mowing of the different turf classifications will be 12 or more per year for fine turf, six to 11 times per year for medium turf and up to five times per year for rough turf.

[Ref. 2]

D. USE OF PGR'S OUTSIDE DOD

The use of PGR's in the public and private sector is widespread. In 1986, 38 states responded to a survey which targeted the use of PGR's as part of their mowing maintenance program. Several states indicated that PGR's played an active role in their program. Other states were dissatisfied with PGR's and used them only experimentally or in a very limited active program. [Ref. 9]

Areas in the private sector which have shown promise from a PGR program include cemetery, golf course and roadside maintenance. Several landscaping firms are also testing PGR's as a cost-saving alternative to frequent pruning of ornamental shrubs and ground cover.

The trend in the public and private sector is for increased use of PGR's. Cost savings through reduced maintenance is cited as the principle reason for using PGR's.

E. TIMING OF APPLICATION

The correct timing of the application of a PGR is crucial to achieving its desired goal. The time of

application will vary each year depending on the morphological stage of plant development. This stage of plant growth will be determined by the recent weather conditions and other factors. A factor which makes the timing of application more difficult is the existence of a mixed turf (polystand). Generally it is recommended that a PGR be applied before the first seedhead emerges. [Ref. 2]

F. FACTORS AFFECTING PGR EFFICACY

A plant's absorption of a PGR will vary. If a PGR is to be foliarly absorbed and the PGR is washed off before sufficient time has elapsed, then its effect may be diminished. The amount of time required for the chemical to be in contact will vary from plant to plant as well as from chemical to chemical.

The efficacy of crown- and/or root-absorbed compounds might be diminished by either too much moisture or too little. Too little moisture would prevent the PGR from being carried to the uptake point in the plant and too much would wash it away.

Climatic factors will also influence PGR uptake by plants. It has been found that a plant will react to its surroundings. This might lead to diminished efficiency in its absorption of the PGR. Evidence of the existence of these climatic factors is supported by studies which show

varying effects of PGR's from one year to the next. [Ref. 2]

G. ECONOMIC BENEFITS FROM PGR'S

The benefits to be realized by an activity using PGR's will vary depending on the pre-PGR frequency of mechanical mowing, cost/acre of maintaining those areas and the cost of PGR application. Possible savings can be found in the areas of fuel, insurance, labor, and equipment maintenance costs. Another factor to consider is that some areas which are maintained by mechanical mowing are subject to erosion. The more frequently these areas are cut, the higher are the costs to repair erosion damage.

A breakeven point for using PGR's will vary depending on a number of factors and input prices but a professionally-acceptable rule of thumb is that the use of a PGR must replace three mowings before it begins to payoff. Chart 1 can be used to estimate the number of mowings which must be eliminated (payback point) before the application of a PGR is cost effective. For example, if an activities mowing cost is \$12 per acre and its estimated cost of PGR application is \$20 per acre do the following to find a payback point:

- Locate the upward sloping line which corresponds to a \$12 per acre mowing cost.
- Locate the point which corresponds to a total PGR application cost of \$20 per acre.

Chart 1

- Extend a horizontal line from the total PGR application cost to a point of intersection with the selected upward sloping line.
- Drop a vertical line from the point of intersection to determine the payback point.

Based on the analysis of this data, the payback point for applying a PGR is approximately two mowings. If the PGR applied cannot save at least two mowings then its application would not be cost effective.

H. NAVAL ACTIVITY USE OF PLANT GROWTH REGULATORS

At the present time the use of PGR's by Naval activities is minimal. The U.S. Army Engineer Waterways Experiment Station in Vicksburg, Mississippi is nearing completion on a three year study to determine the effectiveness of PGR's on grasses at two Naval activities. The activities are Naval Air Station Willow Grove, Pennsylvania and Naval Weapons Station Charleston, South Carolina.

Positive results from this study may lead to more interest on the part of the Navy in using PGR's. At this time the Naval Facilities Engineering Command (NAVFAC) has no policy on the use of PGR's. However, the Program Manager for Facility Support Contracts and Commercial Activities at NAVFAC is interested in the possibility of including an option to use PGR's in future grounds maintenance contract specifications.

III. COST/BENEFIT ANALYSIS

A. NAVAL ACTIVITIES STUDIED

Originally, Naval Air Station Cecil Field, Florida and Naval Weapons Station Crane, Indiana were the activities selected for study. However, when information on the Naval Weapons Station's mowing frequency and cost data were received, consideration of their inclusion in the study was rejected. Based on the nominal, one to three time per year mowing frequency required in different areas, the possibility of reducing the expenditure of grounds maintenance dollars through the use of a PGR was very unlikely [Ref. 4]. Studies have shown the frequency of cutting must typically be once a month or more to make the application of a PGR cost effective.

Due to the rejection of NWS Crane, Indiana as a study candidate, mowing frequency data were obtained from Naval Air Station Jacksonville, Florida [Ref. 5]. NAS Jacksonville and NAS Cecil Field have very similar mowing requirements. The majority of their mowing is in semi-improved areas along runways, roadside right-of-ways and various other areas which do not have fine turf grasses. These candidate areas have mowing requirements of one time per month or greater for five to seven months per year.

B. BASIS OF COST ESTIMATE

NAS Cecil Field's cost estimate was prepared using Engineered Performance Standards (EPS) [Ref. 6]. These standards consider a multitude of factors in the time estimation process. Items such as size of equipment used, location and size of area to be mowed, distance to the job site, and personal time factors are included in the estimation process.

NAS Cecil Field's semi-improved areas (Table 3) were broken into 48 different areas. The number of areas (48) was determined by the number of hours it takes to mow different locations at the activity. The number of hours for each location was determined using EPS. Those areas scheduled for mowing one time per month or more during the period April through October or May through September were selected for the study. Those areas scheduled for less than monthly mowing or those areas scheduled for mowing during the cooler winter months were not considered for the same reason as NWS Crane, Indiana.

NAS Jacksonville's estimate was not prepared in accordance with EPS. A review of a recent NAS Jacksonville mowing contractor's prices indicated the likelihood of a possible imbalance in the submitted schedule of deductions [Ref. 7]. The average mowing price shown for 200 acres of Improved Grounds Care was \$6.10 per acre. The price shown for 670 acres of Semi-Improved Grounds Care was \$4.22 per

acre. Prices for both areas were well below the average EPS based price at NAS Cecil Field which was \$9.78 per acre. Conversation with Public Works personnel at NAS Jacksonville confirmed that these prices were in fact not realistic.

Since NAS Jacksonville and NAS Cecil Field are very similar in their grass-cutting requirements, an average price for NAS Cecil Field's mowing requirements was used as the per acre mowing cost for NAS Jacksonville. The average price of \$9.78 per acre was determined to be reasonable by the Facility Support Contracts personnel at NAS Jacksonville and Southern Division Naval Facilities Engineering Command (SOUTHNAVFACENGCOM) in Charleston, South Carolina. Based on both activity's concurrence, \$9.78 per acre is used as the estimated mowing cost for the study areas at NAS Jacksonville.

The estimated mowing costs per acre at both activities are simple annual costs. They are not based on a net present value (NPV) calculation for more than one year.

C. BASIS FOR UNIT COST OF MOWING

The total average unit cost of mowing per acre includes material, equipment, depreciation and maintenance, labor and contractor overhead and profit. These are the direct costs the government will pay the contractor for mowing performance.

Other costs which the government incurs for the mowing maintenance contracts at the two activities are indirect costs. The costs include expenses for contract preparation, advertisement, award and contract administration. Generally the total costs of these contract support functions are divided among a large number of contracts at both the activity and at the Engineering Field Division (EFD) level. It is not the intent of this study to determine these specific costs and apply them to the unit cost for mowing at each activity.

D. BASIS FOR COST OF PGR APPLICATION

A three-year U.S. Army Engineers Waterways Experiment Study performed at Charleston Naval Weapons Station considered the effects of a PGR program on mowing maintenance costs. This study was used as the basis for the cost/benefit study at NAS Jacksonville and NAS Cecil Field because of the similarities in vegetation and climate.

The three year study (1987, 1988, 1989) showed that the following regimen resulted in effective control of bahiagrass for an average period of ten weeks after application in the Spring [Ref. 8]:

- Mowing the target area (pretreatment mowing) prior to PGR application.
- Application of the Dupont chemical, Oust, at the rate of .5 ounces per acre. (Oust was mixed with the volume of water recommended by the chemical manufacturer.)

The cost of the PGR (\$10/ounce) was obtained from a Dupont representative. The cost of applying the PGR (\$5/acre) was an estimate used in the Corps of Engineers study [Ref. 1].

E. SAMPLE CALCULATIONS FOR MOWING COSTS

Sample Location: NAS Cecil Field

Area for PGR Use: #1

Total Acres: 10

1. Calculation of Grass Cutting Costs W/O PGR Application

Mowing Frequency: 2x/Month (Table 3)

Mowing Cost/Acre: \$8.36 (Table 3)

Time Period Covered: May through September
(Table 3)

Total Mowing Costs for 5 Months:

Mowing Frequency x Time Period Covered x Mowing
Cost/Acre x Total Acres = Total Cost

$$2 \times 5 \times \$8.36 \times 10 = \$836$$

2. Calculation of Grass Cutting Costs W/PGR Application

Mowing Frequency: 2x/Month (Table 3)

Mowing Cost/Acre: \$8.36 (Table 3)

Time Period Covered: May through September
(Table 3)

PGR Chemical: Oust (Dupont Chemical)

Recommended Rate of Application: .5 Ounce/Acre

Cost of PGR: \$10/Ounce

Cost of Pretreatment Mowing: \$8.36/Acre

Cost of PGR Application: \$5/Acre

Average Duration of PGR Effectiveness: 10 Weeks

Additional Mowings Required for Area Based on 10
Week

Effective Period: 5

Total Mowing Costs for 5 Months:

(Cost/Acre for Pretreatment Mowing + Cost/Acre for
PGR + Cost/Acre for PGR Application) x Total Acres +
(Mowing Cost/Acre x Total Acres x Additional Mowings
Required After PGR Loses Effectiveness) = Total
Mowing Cost

$(\$8.36 + \$5 + \$5) \times 10 + (\$8.36 \times 10 \times 5) = \602

(Rounded to Nearest Whole Dollar)

Total Savings Using PGR:

Total Mowing Costs W/O PGR - Total Mowing Costs

W/PGR = Total Cost Savings

$\$836 - \$602 = \$234$

% Savings Using PGR:

Total Savings Using PGR/Total Mowing Costs W/O PGR =

% Savings

$\$234/\$836 = 28\%$ (Rounded to Nearest Whole Percent)

F. SUMMARY OF PGR EFFECTIVENESS AT NAS CECIL FIELD

An analysis of the costs of current mowing practices
versus the predicted costs using a PGR shows significant

savings can be realized if a PGR application program is implemented.

The total cost of current mowing practices in the areas studied is \$107,390 per year. The cost of mowing the same areas when using a PGR would be \$92,038. The \$15,352 (14%) savings is significant (Table 5).

The estimated percent savings using a PGR application program range from a high of 32% in an area when the frequency of mowing is two times per month and at a cost of \$12.36 per acre to a low of -2% (loss) when the frequency of cutting is one time per month at a cost of \$8.91 per acre (Table 3).

The average savings using a PGR application program in areas cut more frequently than one time per month is nearly 29%. The average savings on PGR treated areas where the frequency of cutting is one time per month is less than 1%.

G. SUMMARY OF PGR EFFECTIVENESS AT NAS JACKSONVILLE

The analysis of NAS Jacksonville's mowing costs is somewhat easier than an analysis of NAS Cecil Field's primarily because NAS Jacksonville has two principle mowing areas to study versus the 48 at Cecil Field. Level I (Improved Grounds Care) totals 200 acres and is to be mowed once per week during the period March through October. Level II (Semi-Improved Grounds Care) totals 670 acres and

is to be mowed two times per month during the period March through October.

Since NAS Jacksonville had not prepared an independent government estimate based on Engineered Performance Standards (EPS), an average mowing cost per acre of similar areas at NAS Cecil Field (Table 3) is used for analysis purposes. If NAS Jacksonville implements a PGR application program in the future, a detailed estimate of the different mowing areas should be performed using EPS. This will identify the locations, based on a per acre cost, where a cost savings can be realized by applying a PGR. The \$9.78 per acre mowing cost is considered acceptable by both NAS Jacksonville and Southern Division Naval Facilities Engineering Command (SOUTHNAVFACENGCOM) facility support contract personnel.

An analysis of the current mowing practices at NAS Jacksonville versus the predicted costs using a PGR (Table 4) show significant savings can be realized if a PGR application program were implemented.

The total costs of current mowing practices in the areas studied is \$167,434 per year. The cost of mowing the same areas is predicted to be \$132,319 when utilizing a PGR application program. The \$35,115 (21%) savings is significant. The percent savings using a PGR range from a high of 24.9% when mowing four times per month to 18.6% when mowing two times per month (Table 4).

H. SUMMARY OF RESULTS

The cost/benefit study shows that both NAS Cecil Field and NAS Jacksonville can benefit from a PGR application program. Based on the use of the PGR, Oust, a ten week effective period after application, and the estimated per acre mowing costs, NAS Cecil Field and NAS Jacksonville could realize a mowing maintenance cost reduction of \$15,352 (14%) and \$35,115 (21%) respectively (Table 5).

It is important to realize the actual savings will vary depending on the actual effective period of the PGR, the actual cost of PGR application and the actual mowing costs per acre.

IV. CONCLUSIONS AND RECOMMENDATIONS

The intent of this thesis was to determine, based on cost estimates and mowing requirements, whether the application of a PGR could theoretically save two Naval activities grounds' maintenance dollars.

The results indicate considerable cost savings can be realized at both Naval Air Station Cecil Field and Naval Air Station Jacksonville if a well-planned PGR application program is implemented. This program must consider the present mowing costs, frequency of mowing, cost of PGR application and the effectiveness of the PGR applied.

The highest potential savings are in areas where the frequency of mowing is weekly or biweekly. In areas where the mowing frequency is one time per month, the savings approach a breakeven point. However, a PGR program can be beneficial in the less-frequently mowed areas (one time per month) if the frequency of mowing creates erosion problems or the areas are dangerous to mow. An analysis on erosion and safety-related problems was not considered in this theses.

The timing of PGR application, proper turf preparation (premowing), and weather conditions are crucial to the effectiveness of a PGR. The application of the right

chemical at the wrong time on improperly prepared turf can eliminate the possibility of any cost savings. [Ref. 2]

All Naval activities which mow a significant amount of semi-improved acreage should consider using PGR's. This PGR program should be developed and monitored by individuals who have knowledge of turf grasses and PGR's peculiar to their geographic location. Assistance can be provided by a number of sources which include NAVFAC's Engineering Field Divisions, the U.S. Army Engineers Waterways Experiment Station Environmental Laboratory in Vicksburg, Mississippi or knowledgeable experts in the private sector.

TABLE 2
SUMMARY OF MOWING ACTIVITIES AT NAVAL AIR STATION
JACKSONVILLE, FLORIDA

Mowing Category	Site Description	No. of Acres	Mowing Frequency	Cost of Mowing/Acre
Level I	Various areas NAS	200	4x/Month Mar-Oct	*\$9.78
Level II	Various areas	670	2x/Month Mar-Oct	*\$9.78

* The mowing cost/acre for Naval Air Station Jacksonville, Florida is based on the average cost/acre for mowing similar areas at Naval Air Station Cecil Field, Florida. Cecil Field's costs were estimated using NAVFAC P-712.0, Engineered Performance Standards for Roads, Grounds, Pest Control and Refuse Collection Handbook.

TABLE 3

EXPECTED MOWING AND PGR TREATMENT COSTS FOR VARIOUS
SELECTED AREAS AT NAVAL AIR STATION CECIL FIELD,
FLORIDA FOR PERIODS INDICATED

Mowing Frequency	2x/Month May-Sept	2x/Month May-Sept	2x/Month May-Sept	2x/Month May-Sept

Acres	10	47	5.25	22
Mowing Cost/Acre	\$8.36	\$9.19	\$11.68	\$10.14
Total Mowing Cost W/O PGR	\$836	\$4319	\$613	\$2231
Total Mowing Cost W/PGR*	\$602	\$3062	\$420	\$1558
Savings (\$)	234	1257	193	673
% Savings	28	29	31	30

* Total mowing cost W/PGR, for the purpose of this study, includes one initial mowing prior to application of PGR, PGR application cost, cost of PGR, and any additional mowings required following effective period of PGR. The effective period of the selected PGR is ten weeks. This period is based on a three year study at Charleston Naval Weapons Station performed by Linda S. Nelson with U.S. Army Engineer Waterways Experiment Station Vicksburg, Mississippi.

% Savings	27	4	2	<2>

* When calculating total mowing costs W/PGR application in areas receiving 1x/month mowing Apr-Oct, five additional cuttings beyond effective period of PGR were used.

** Area #5 is a magazine slope area. Cost of application is estimated at \$20/acre + precutting and chemical costs.
